

Task Goal: Create an ETL process to transfer data from a Staging table to the DWH tables.

Expected result: one file with the SQL script.

1. Use the script from the file HT1_part1.sql to create the DWH tables and the Staging table.

Populate the Dim_Gym and Dim_Member tables and add initial data to the Staging table.

2. Write a set of commands to transfer data from the Staging table to the DWH tables. This set of commands can be implemented as either a script, a function or a procedure.

- Populate the missing values in the Dim_date table.
- Handle duplicate data appropriately.
- Calculate the duration of each visit in minutes using the Time_in and Time_out columns.
- Calculate the value for the Day_part column using the Time_in values.

Based on the following ranges:

Up to 10:00 - Morning

10:01 to 17:00 - Day

After 17:01 – Evening

- Note that the information about a visit to Gym_1 is stored in a single row. For Gym_2, the information is stored in two rows: the first row contains the Time_in value, and the second row for the same visitor contains the Time_out value.
- Transfer to the DWH tables only completed visits - those with a specified Time_out value.
- Verify that the personal_code matches the visitor's name and exclude any incorrect data from processing.
- Note that Gym_1 stores names as <last name> <first name>, while Gym_2 stores names as <first name> <last name>.
- Mark the rows with errors or those that cannot be processed. You may either extend the existing Staging table or create a separate table to store such rows.
- Remove the processed rows from the Staging table.

3. Use the script HT1_part_2.sql to add a new set of data to the Staging table. Ensure that your ETL script processes the new rows correctly.
